

Suicide and self-harm in Ireland: Data collection systems and recent outcomes

Technical Meeting on Suicide and Self-Harm Monitoring and Prevention in the
Russian Federation

Stavropol State Medical University,
28-30th October 2019

Prof Ella Arensman

School of Public Health & National Suicide Research Foundation,
WHO Collaborating Centre on Surveillance and Research in Suicide Prevention
University College Cork, Ireland
Australian Institute for Suicide Research and Prevention
International Association for Suicide Prevention

Overview

- Recent trends of suicide in Ireland
- Challenges in relation to accuracy and real-time access to suicide mortality data
- Suicide Support and Information System and Suicide and Self-Harm Observatory – recent outcomes
- National Self-Harm Registry of Self-Harm Ireland – recent outcomes
- Benefits of suicide and self-harm surveillance systems

Trends in suicide in Ireland by gender, 2002-2017

2016-2017: Provisional data CSO

Suicide in Ireland by age and gender: Average rates

Connecting for Life: Ireland's National Strategy to Reduce Suicide 2015-2020

Goal 7: To improve surveillance, evaluation and high quality research relating to suicidal behaviour

7.2: Improve access to timely and high quality data on suicide and self-harm

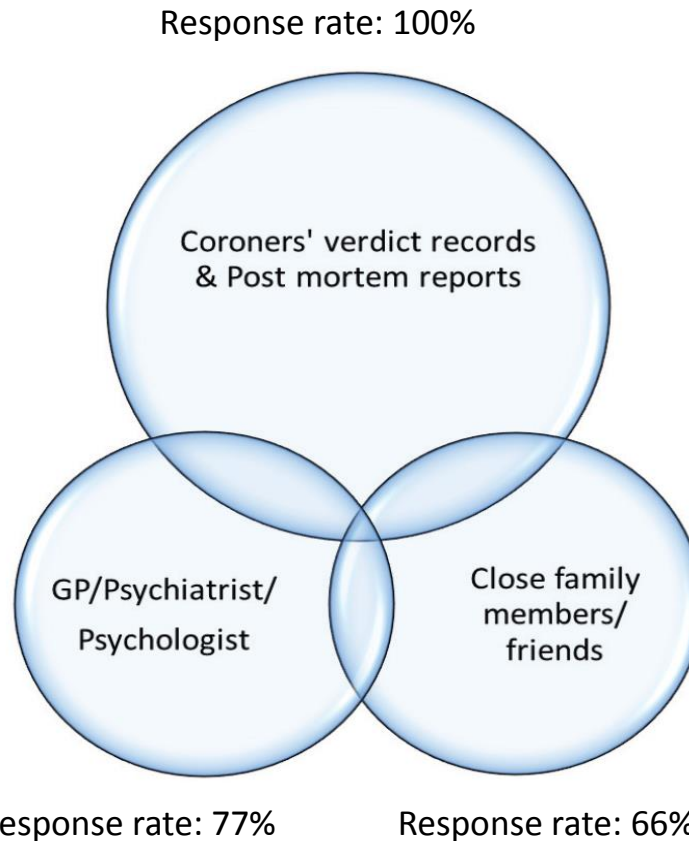

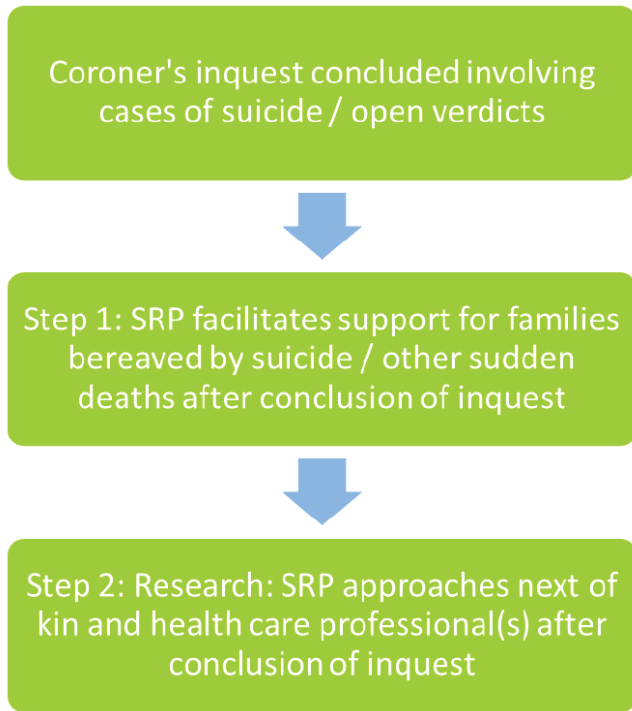

The need to develop an innovative suicide recording system in Ireland: Suicide Support and Information System (SSIS)

- Absence of real-time data on suicide. Suicide figures are often published by the Central Statistics Office (CSO) 2 years after the death has occurred.
- Information from CSO is often limited to demographics and methods involved in cause of death

Development of the Suicide Support and Information System – Objectives:

1. Better define the incidence and pattern of suicide in Ireland
2. Identify and better understand causes of suicide
3. Identify and improve the response to clusters of suicide
4. Improve access to support for the bereaved
5. Reliably identify those individuals who present to the Emergency Department due to self-harm and who subsequently die by suicide

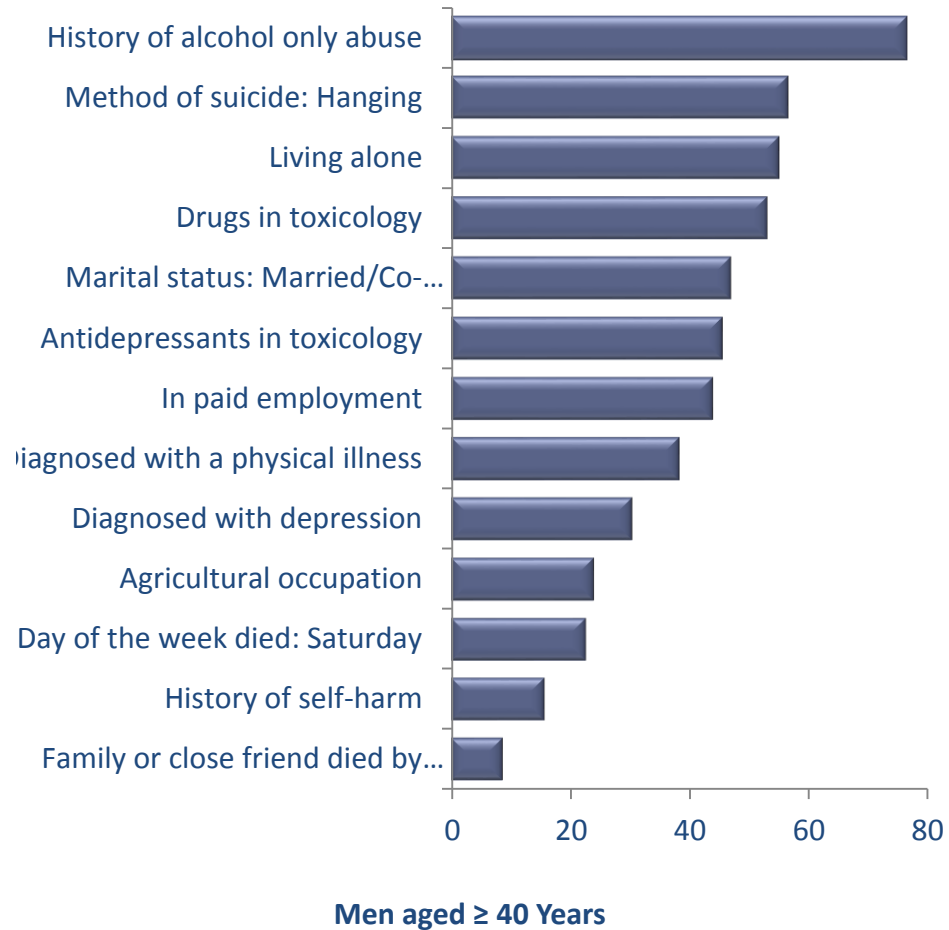

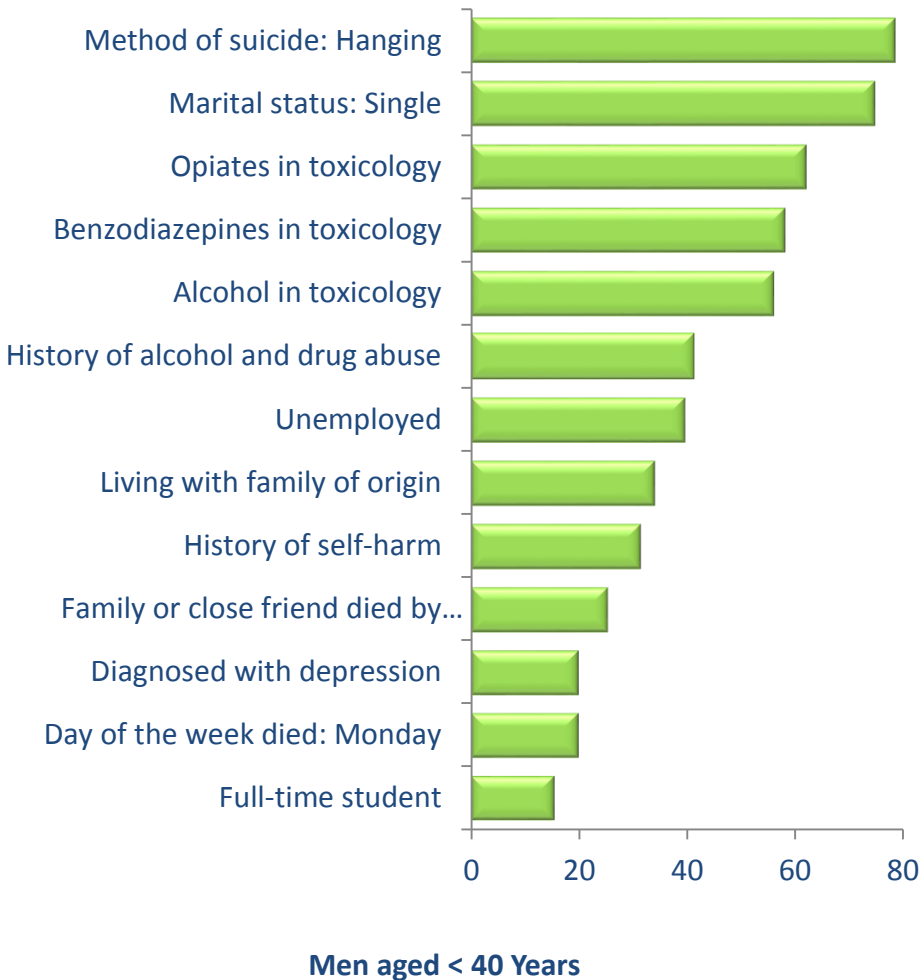

A systematic approach to obtain real-time and accurate data on suicide: Suicide Support and Information System, Ireland

Main characteristics of people who had died by suicide

- Overrepresentation of men (80.1%); Men significantly younger than women
- Relatively high proportion were unemployed at time of death (33.1%)
- Among men, 48.6% had worked in the construction/production sector; among women, 26.5% had worked in a healthcare setting
- Nearly two thirds had a history of self-harm (65.2%); 69.1% were diagnosed with depression, and alcohol/and or drug abuse was present among 60.7%
- In the year prior to death, 81% had been in contact with their GP or a mental health service. Most people who contacted GP did so more than 4 times

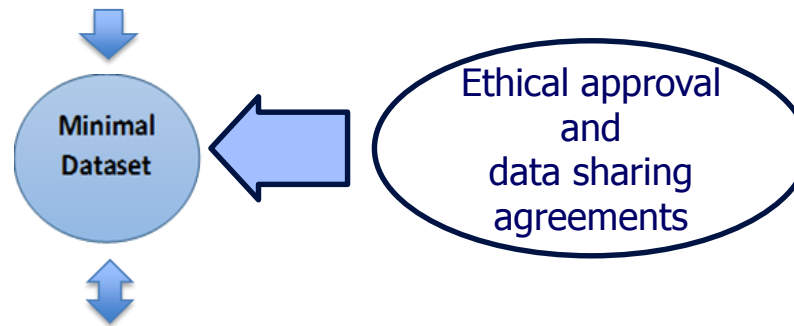

Differences between men aged <40 years versus men aged ≥ 40 years

The Suicide and Self-Harm Observatory (SSHO)– Links between data sources to capture suspected suicide case in real-time

The Coroners of Cork city and county

- Only information that can be provided prior to coronial request will be made available by the coroner for entry to the minimal dataset.
- Information provided by the coroners will not be used by the NSRF/UCC to approach family members directly
- Data obtained from the coroners will provide the most complete information on case of suspected suicide

Health Service Executive

- A two way pathway will exist between the NSRF and the HSE:
 1. Information relating to the suspected suicide of a service user will be obtained from the HSE patient mortality register.
 2. Information from the minimal dataset will be shared with the Suicide Resource Officer (SRO) in order to facilitate early response to emerging suicide clusters.
- The SRO takes into consideration families in need due to the sudden death of a family member based on best practice.
- The SRO also provides support to schools and other community services in the region that has been affected by the sudden death of a student.

Benefits of the SSHO based on pilot implementation December 2018-September 2019

- SSHO has been effective in crosschecking incomplete data provided by the HSE Resource Officer for Suicide Prevention. The crosschecking feature of the SSHO ensures that support can be provided indirectly by the HSE in affected communities.
- Communication between the primary researcher and the data providers has been good overall.
- The SSHO has been used in five instances within the first six months of its existence to validate unverified reports of contagion within two areas of Cork in December 2018 and May 2019.
- This validation feature has also been effective in fulfilling a request from the media for verification of information, hence preventing the spread of misinformation relating to perceived contagion/clustering in the area of Cork.

The National Self-Harm Registry Ireland – Recent outcomes

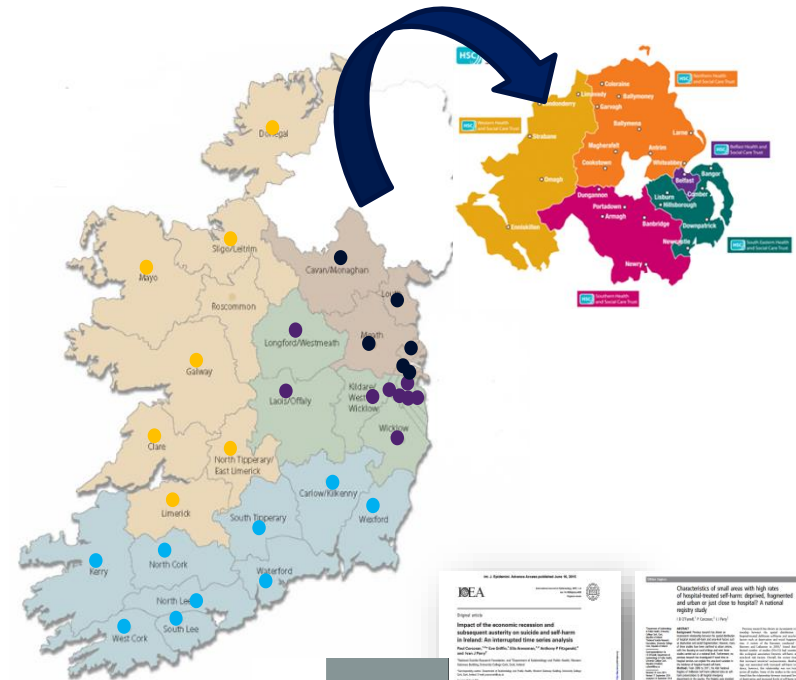

National Self-Harm Registry Ireland

Aims:

- To **establish the extent and nature** of hospital-treated self-harm;
- To **monitor trends over time** and also by area;
- To **contribute to policy and development**;
- To **inform the progress of research and prevention**.

Definition

‘an act with **non-fatal outcome** in which an individual **deliberately initiates a non-habitual behaviour**, that without intervention from others will cause self harm, or deliberately ingests a substance in excess of the prescribed or generally recognised therapeutic dosage, and which is aimed at realising changes that the person desires via the actual or expected physical consequences’.

Abstract

Purpose Rates of hospital-treated self-harm are highest among young people. The current study examined trends in rates of self-harm among young people in Ireland over a 10-year period, as well as trends in self-harm methods.

Methods Data from the National Self-Harm Registry Ireland on presentations to hospital emergency departments (EDs) following self-harm by those aged 10–24 years during the period 2007–2016 were included. We calculated annual self-harm rates per 100,000 by age, gender and method of self-harm. Poisson regression models were used to examine trends in rates of self-harm.

Results The average person-based rate of self-harm among 10–24-year-olds was 318 per 100,000. Peak rates were observed among 15–19-year-old females (564 per 100,000) and 20–24-year-old males (448 per 100,000). Between 2007 and 2016, rates of self-harm increased by 22%, with increases most pronounced for females and those aged 10–14 years. There were marked increases in specific methods of self-harm, including those associated with high lethality.

Conclusions The findings indicate that the age of onset of self-harm is decreasing. Increasing rates of self-harm, along with increases in highly lethal methods, indicate that targeted interventions in key transition stages for young people are warranted.

Self-harm among young people in Ireland, 2007–2016

Male

Female

Abstract
Background Repeated self-harm represents the single strongest risk factor for suicide. To date no study with the exception of one, has measured the extent of hospital admission presentations due to self-harm among young people.
Methods An 18-month self-harm presentation series obtained from the National Self-Harm Register related to emergency admissions in Ireland (2007–2016) was analysed. Risk of repeat self-harm was assessed from clinical analysis of case information across the order of presentation and gender, including young people under 25.
Results The total sample comprised 16,793 individuals involving 40,882 presentations. Repeated self-harm was the most common method (77.9%). Duration of self-harm ranged from 10 min to 10 days. The risk of repeat self-harm presentations increased with age, with the highest risk observed in 15–19-year-old females and 20–24-year-old males. Those who used self-cutting were at higher risk for repetition than those who used overdose. Individuals with a history of self-harm were significantly more likely to present with self-harm than those who had never presented with self-harm. The risk of repeat self-harm was significantly higher in young people aged 15–19 years with repeated self-harm in the most recent year than in those aged 20–24 years with repeated self-harm in the most recent year. The number of presentations increased with the number of previous presentations. The highest risk of repeat self-harm was observed among high frequency repeaters (more than 4 in 12 months). In presentations where the patient presented with high frequency repeaters (more than 4 in 12 months) the risk of repeat self-harm was significantly higher than in those who presented with low frequency repeaters (1–4 in 12 months). The highest risk of repeat self-harm was observed in young people at subsequent presentations. The highest risk of repeat self-harm was observed in young people at subsequent presentations. The highest risk of repeat self-harm was observed in young people at subsequent presentations.
Conclusions Self-harm, repeated self-harm, young people, emergency admissions, self-harm method

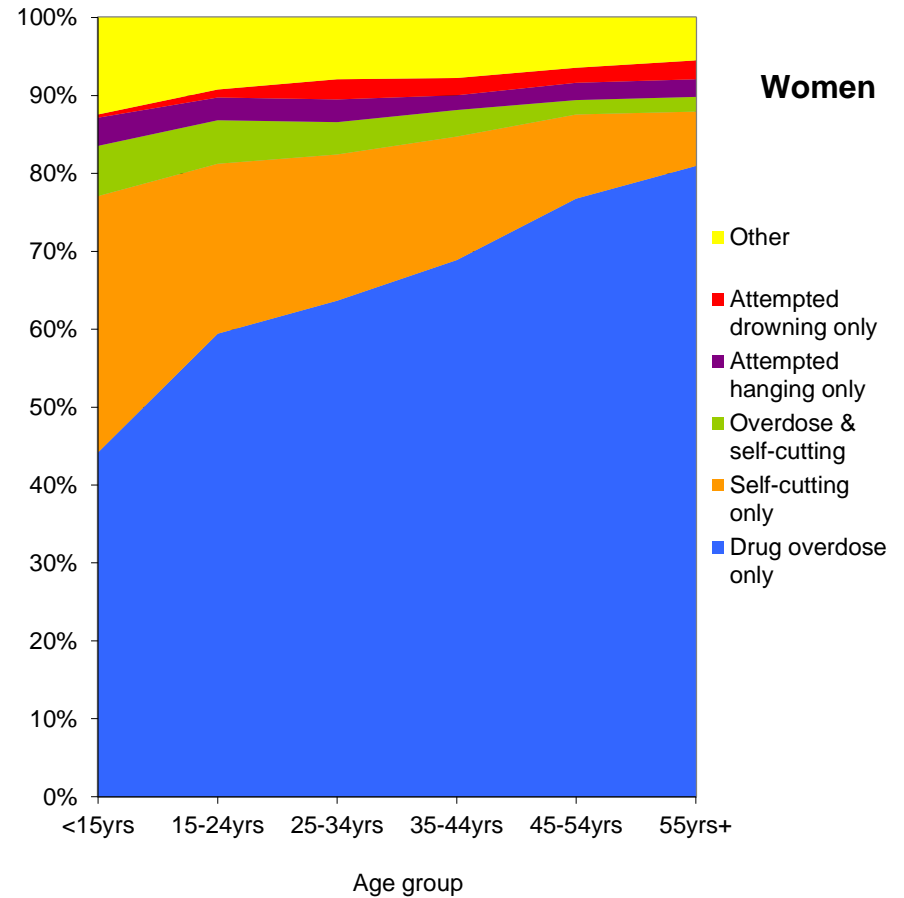

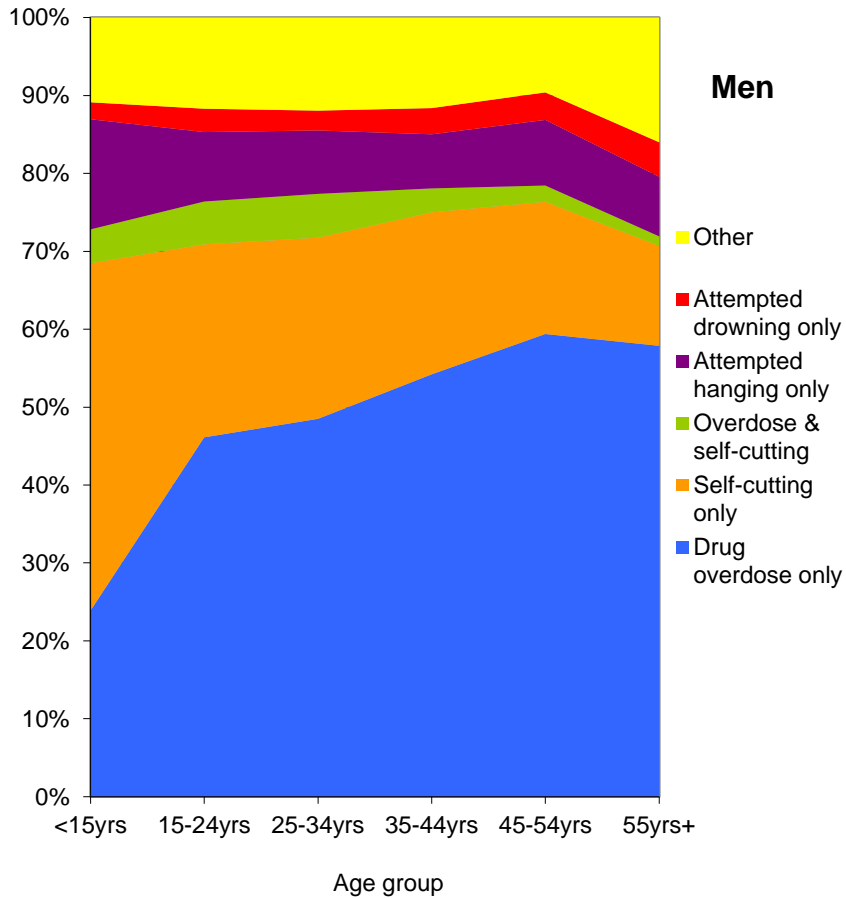

Risk of repeated self-harm in young people

- Young people with the highest risk for repeated self-harm were 15–19-year-old females and 20–24-year-old males
- Self-cutting was the method associated with the highest risk of self-harm repetition. Time between first self-harm presentations represents an indicator of subsequent repetition
- Increased risk of self-harm method escalation among young people in recent years

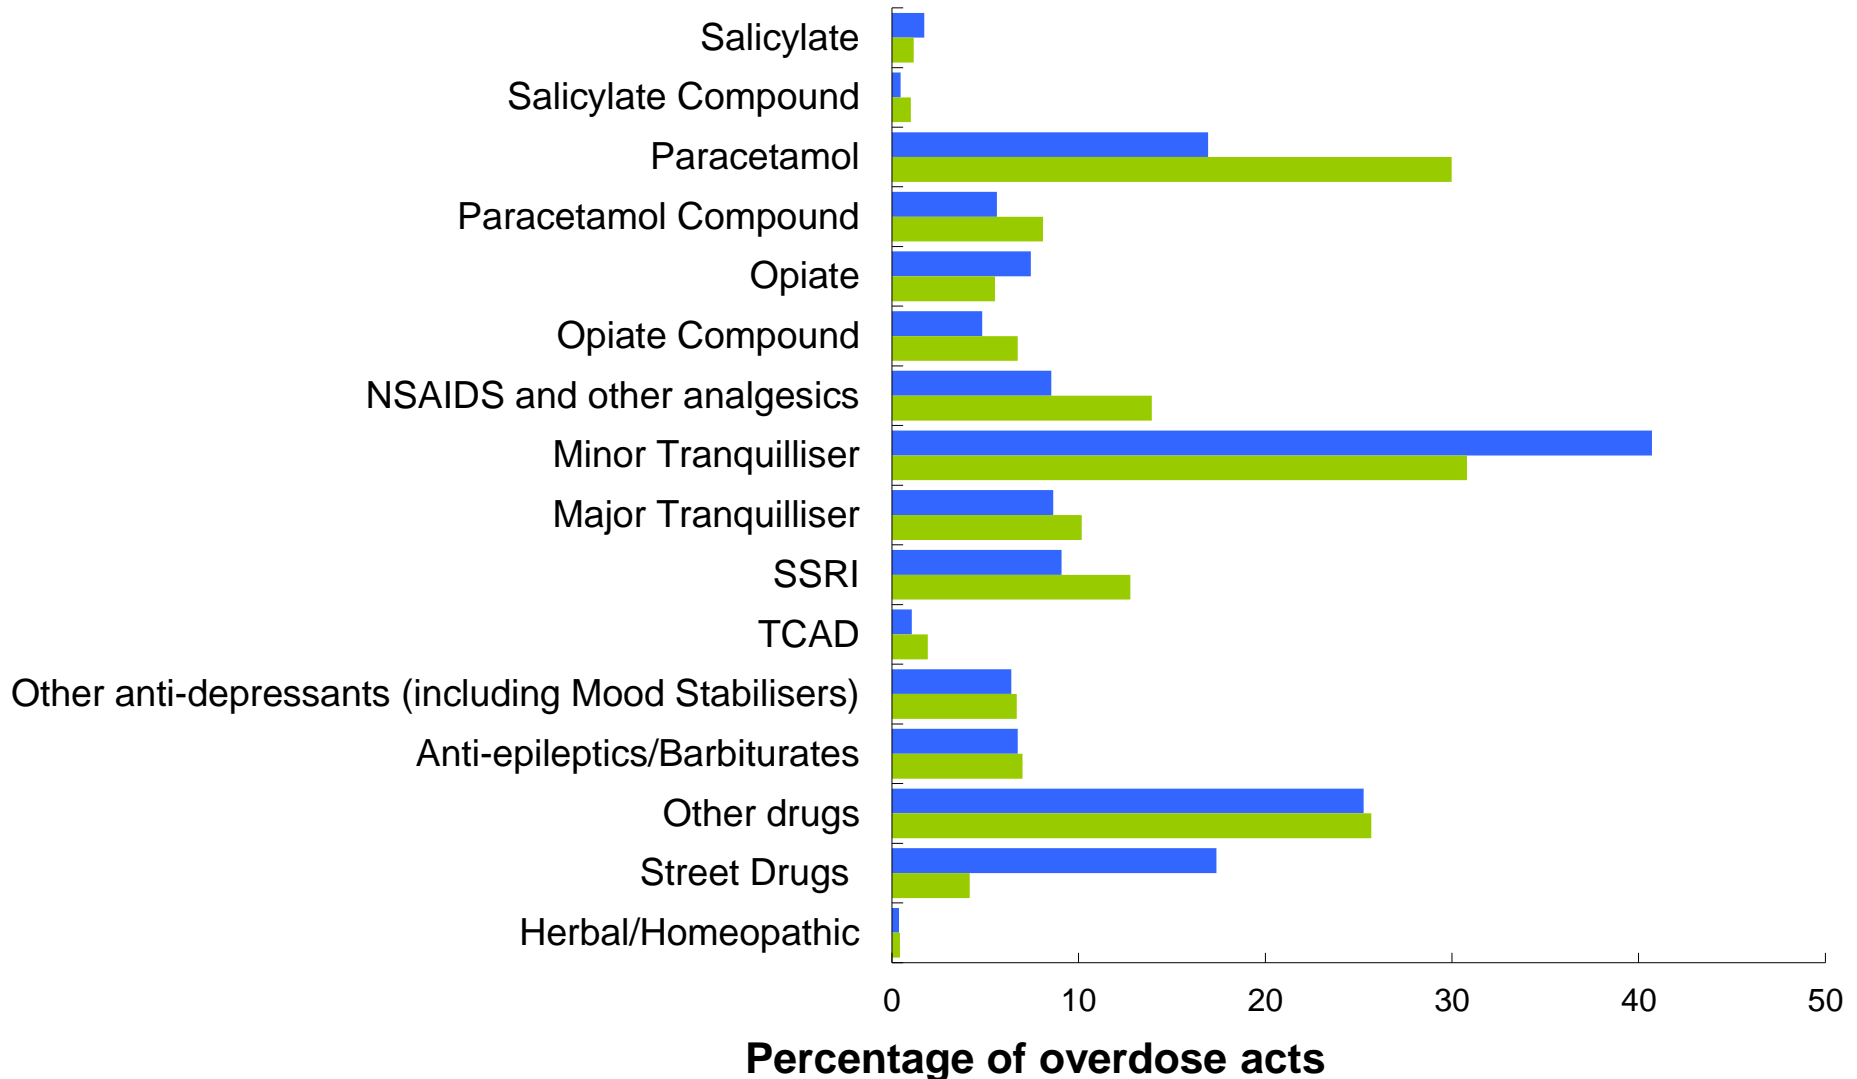

Trends in highly lethal self-harm methods

Method of self-harm by males and females by age group

Drugs used in intentional overdose

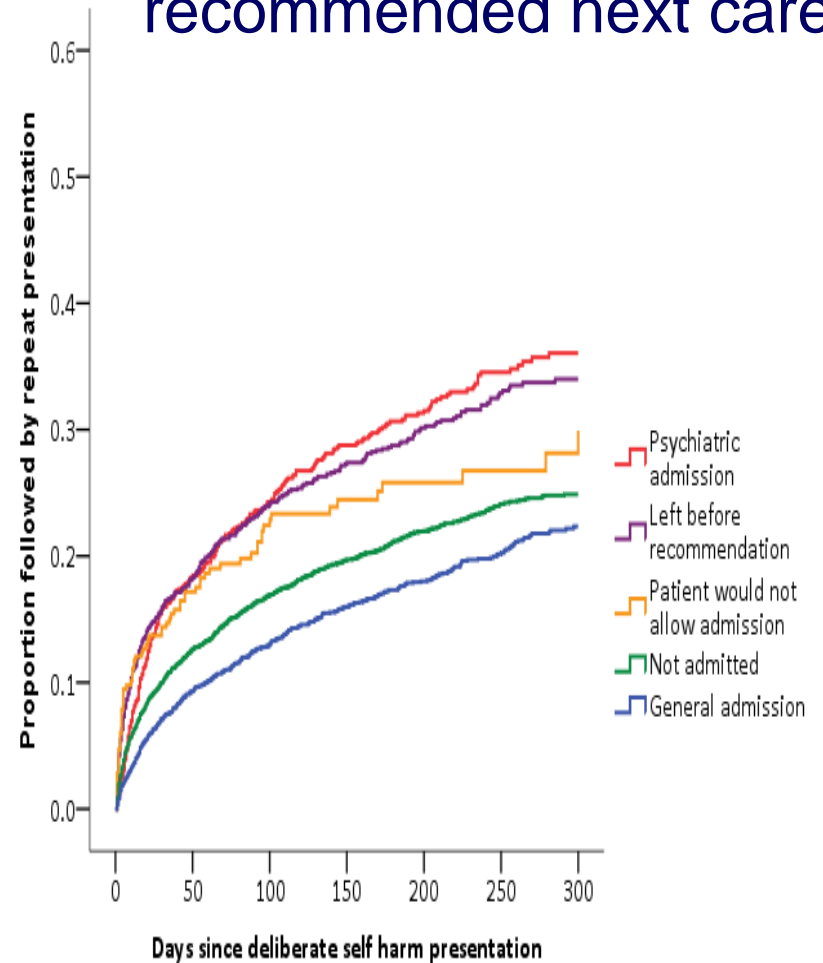

Percentage of overdose acts

Repetition by number of self-harm presentations

Repetition of self-harm by recommended next care

Self-harm intervention and suicide prevention at national level in Ireland

- National Clinical Programme for the Assessment and Management of Patients Presenting to Emergency Departments following Self-Harm
- *Connecting for Life*, Ireland's National Strategy to Reduce Suicide, 2015-2020

2018 Statistics at a Glance

Presentations **12,588**
Persons **9,785**

Rates in young people aged 10-24 years increased by 29% between 2007-2018

RATES:

210
per 100,000
1 in every 476
had a self-harm act

Male: 20-24 year-olds
(543 per 100,000)
1 in every 184

Female: 15-19 year-olds
(766 per 100,000)
1 in every 131

PEAK RATES WERE AMONG YOUNG PEOPLE

TIME:

Peak time

Almost **half (44%)** of presentations were made between 7pm-3am

Monday, Tuesday and Sunday had the highest number of self-harm presentations

METHOD:

2 in every 3 involved **overdose**

3 in every 10 involved **alcohol**

Men

Women

3 in every 10 involved **self-cutting**

TREATMENT:

72% received an assessment in the ED

79% received a follow-up recommendation after discharge

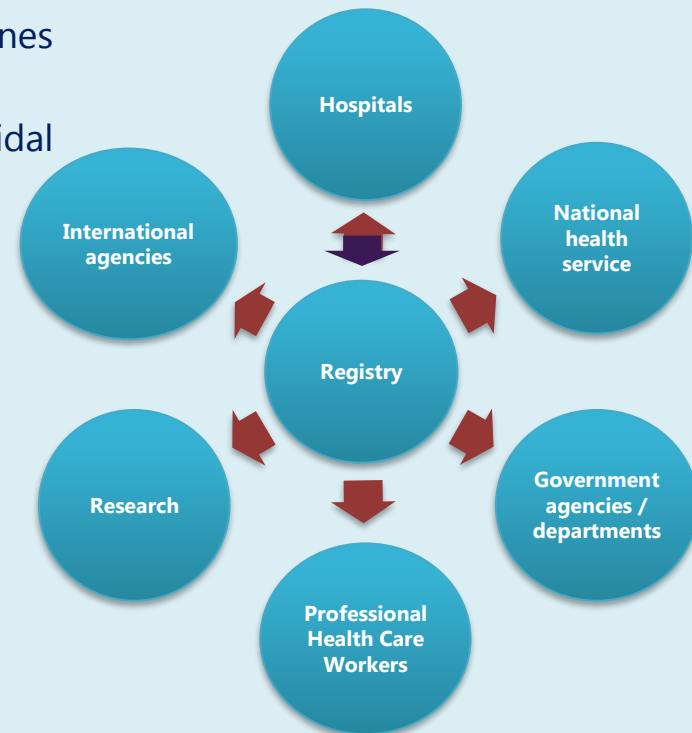

13% left ED before a recommendation was made

1 in 7 persons had a repeat attendance in 2018

Benefits of surveillance systems for hospital/health centre treated self-harm

- Informing:
 - Service provision, resource deployment and guidelines for self-harm management
 - Assessment and interventions for non-fatal suicidal behaviour
- “Real-Time Data”
- Evaluation of interventions
- Regional variations
- Clinical management of self-harm
- All attendances to hospital Emergency Departments

Thank you!
благодарю вас!
